

MicroFocus Fortify vs GitLab

GitLab compared to other DevOps tools

Both Fortify and GitLab Ultimate offer open source component scanning along with Static and Dynamic Application Security Testing. Fortify uses Sonatype for open source scanning in its SaaS product and BlackDuck for open source scanning on-premise.

Fortify is a mature product and has led the Gartner Magic Quadrant for application security testing every year. Fortify offers IAST (with DAST) and RASP, though it does not offer container scanning. In spite of its strengths as a stand-alone product, Fortify is a separate process outside of the developer's merge request workflow.

GitLab automatically includes broad security scanning with every code commit including Static and Dynamic Application Security Testing, along with dependency scanning, container scanning, and license management.

FEATURES

Static Application Security Testing

GitLab allows easily running Static Application Security Testing (SAST) in CI/CD pipelines; checking for vulnerable source code or well known security bugs in the libraries that are included by the application. Results are then shown in the Merge Request and in the Pipeline view. This feature is available as part of [Auto DevOps](https://docs.gitlab.com/ee/topics/autodevops/#auto-sast) to provide security-by-default.

Dependency Scanning

GitLab automatically detects well known security bugs in the libraries that are included by the application, protecting your application from vulnerabilities that affect dependencies that are used dynamically. Results are then shown in the Merge Request and in the Pipeline view. This feature is available as part of [Auto DevOps](https://docs.gitlab.com/ee/topics/autodevops/#auto-dependency-scanning) to provide security-by-default.

Container Scanning

When building a Docker image for your application, GitLab can run a security scan to ensure it does not have any known vulnerability in the environment where your code is shipped. Results are then shown in the Merge Request and in the Pipeline view. This feature is available as part of [Auto DevOps](https://docs.gitlab.com/ee/topics/autodevops/#auto-container-scanning) to provide security-by-default.

Dynamic Application Security Testing

Once your application is online, GitLab allows running Dynamic Application Security Testing (DAST) in CI/CD pipelines; your application will be scanned to ensure threats like XSS or broken authentication flaws are not affecting it. Results are then shown in the Merge Request and in the Pipeline view. This feature is available as part of [Auto DevOps] (<https://docs.gitlab.com/ee/topics/autodevops/#auto-sast>) to provide security-by-default.

Interactive Application Security Testing

[IAST](https://blogs.gartner.com/neil_macdonald/2012/01/30/interactive-application-security-testing/) combines elements of static and dynamic application security testing methods to improve the overall quality of the results. IAST typically uses an agent to instrument the application to monitor library calls and more. GitLab does not yet offer this feature.

Runtime Application Security Testing

RASP uses an agent to instrument the application to monitor library calls as the application is running in production. Unlike other security tools, RASP can take action to block threats in real-time, similar to a Web Application Firewall but from within the app's runtime environment rather than at the network layer. GitLab does not yet offer this feature.

License Management

Check that licenses of your dependencies are compatible with your application, and approve or blacklist them. Results are then shown in the Merge Request and in the Pipeline view.
